Abstract

An inventory of family Noctuidae belonging to superfamily Noctuoidea has been prepared from Himachal Pradesh. As many as 2300 representatives of 105 species referable to 69 genera have been studied and 10 species have been recorded for the first time from this area.

Key words : *Lepidoptera, Agricultural pests, Himachal Pradesh, Inventory, moths.*

Introduction:

Lepidopteran species are characterized as being covered with pigmented scales all over the wings, having two large compound eyes and siphoning type of mouth parts with an elongated proboscis. Noctuidae is the largest family of order Lepidoptera which accounts for 24801 described species (Heppner 1991) and can be easily identified on the basis of wing venation of hind wing, where Sc+R₁ is separated from R₅ and is connected with discal cell at base. This group of moths is of immense economic importance as the caterpillars of many species are serious agricultural pests and attack variety of agricultural and forest plants.

During the recent survey cum collection tours, as many as 2300 adult moths belonging to 105 species and referable to 69 genera, viz. , have been studied and authentically identified following (Hampson, 1894, 1905) and by comparison of collections lying in the museums of Forest Research Institute, Dehradun and Indian Agriculture Research Institute, PUSA, New Delhi. Comparison has also been made with the types of Natural History Museum, London. The primary objective of the present communication is to an inventory with, authentic identification, first reference, type species, material examined, distribution and remarks, if any, of all included species.

Materials and Methods

The study was conducted during intensive and extensive survey cum collection tours in the far flung localities of Himachal Pradesh between July 2012 to November 2014 which yielded a collection of 2300 adult representatives of family Noctuidae. The entire materials were collected from light traps using a 40W ultraviolet light suspended on one side of a vertical white sheet (approximately 2.0m x 2.5m). Sometimes a portable light trap or petromax lamp (during failure of electricity) was also used. Various sampling sites in different localities of Himachal Pradesh were surveyed exclusively during this period. The adult representatives of different species were collected and killed with ethyl acetate vapours in insect killing jars of different sizes, depending upon the size of the specimen. In order to keep the scales intact on the body of the moths, they were removed from the bottles as soon as they were killed. Each of the killed specimens was pinned properly. This was preceded by spreading of both the wings on the insect stretching board, followed by their drying. Each specimen was labelled. The specimens were preserved in airtight boxes, having naphthalene balls as fumigants. Various morphological characters, such as head appendages, wing maculation, wing venation and genitalia, were examined to identify different species.

Result and Discussion:

In present study 105 species belonging to 69 genera have been collected. The list of all the identified species along with first reference, type species, material examined and old distribution are provided below. The work involved study and examination of various morphological characters such as antennae, legs, labial palpi and wing maculation. External male and female genitalia were also dissected in order to identify sibling species. The authentic identification was done by comparisons with the reference collections lying at Natural History Museum, London, Forest Research Institute, Dehradun and Indian Agriculture Research Institute, PUSA, New Delhi.
